

Innovations

Movie App innovations

- Added a floating heart Icon button to the reusable movie card component that updates the favourites list as well as changing it's state based on if the movie is in the favourites list. It will show a filled icon heart if it is a favourite movie and an outline-heart when not.
- The homepage has the option of showing not just the trending movies but upcoming movies, currently playing movies and top rated movies from the TMDb. They are selected by buttons that work as a makeshift tab, I was going for like a bootstrap pills/tabs navigation element. I didn't want to use the ion-tab element because a bottom row tabs should be for primary actions like navigating to the favourites page or a search page, but since we do these actions in the header of the pages it doesn't make sense contextually to use. Each method to load the content has it's own API call it fires off, and I added a ion-loader element to show the user something is loading after they change content. Each one has a customer loading message, and is dismissed after the API call is complete.
- Added a responsive grid layout to the home page and favourites page to make the app mobile and desktop friendly.
- On the favourites page I added an ion-refresher so that after the user changes a favourite movie without clicking into the movie-details page, the user can update the favourites list without hard refreshing the browser by pulling down the refresher. This part might be more intuitive on mobile but it works fine with a mouse too.
- On the movie card component, I made the whole card component clickable, but added in a floating label to identify this to the user. I also added in some nice transition animations. When hovered the image will scale slightly with some nice easing, the box-shadow will grow slowly, and the floating label will position itself in the bottom right corner of the card. This substitutes in for the "Details Button movie. When the *Details* button is pressed, Movie Details page should be open for that" as the functionality is the same, the click targets of the cards is just a lot bigger than a small button so it make's it more usable.
- On the details and movie-details page the lists of cast/crew/movie credits are capped at 5 per list. These can then be expanded further by pressing the custom "See more +" ion-items that are acting as buttons. There is also some nice

handling of missing people profile pictures in the cast & credits section and it will display an icon in it's place.

- On the homepage when a movie doesn't have a poster image available a replacement with the words "Not found" shall be shown.
- On the searchbar the user can fire the search by pressing the enter bar or by using the search button, this is done with using `keydown.enter` to look for enter being hit and not just firing the event on `ionInput` which would fire too many API calls one with each keypress, or on `ionChange` which would fire on blur too but the user might have typed and then not wanted to navigate elsewhere and also it would render the search button useless which was a requirement. So this was my solution. We can hit enter or Press the search button.
- I added some interfaces for Data that was being used in the app in `app/models/credits.ts`.
